Chapter 1

Introduction

*hypre* is a software library for solving large, sparse linear systems of equations on massively parallel computers. The library was created with the primary goal of providing users with advanced parallel preconditioners. Issues of robustness, ease of use, flexibility, and interoperability also play an important role.

1.1 Features

- **Scalable preconditioners provide efficient solution on today’s and tomorrow’s systems**: *hypre* contains several families of preconditioner algorithms focused on the scalable solution of very large sparse linear systems. *hypre* includes “grey-box” algorithms that use more than just the matrix to solve certain classes of problems more efficiently than general-purpose libraries. This includes algorithms such as structured multigrid.

- **Suite of common iterative methods provides options for a spectrum of problems**: *hypre* provides several of the most commonly used Krylov-based iterative methods to be used in conjunction with its scalable preconditioners. This includes methods for nonsymmetric systems such as GMRES and methods for symmetric matrices such as Conjugate Gradient.

- **Intuitive grid-centric interfaces obviate need for complicated data structures and provide access to advanced solvers**: *hypre* has made a major step forward in usability from earlier generations of sparse linear solver libraries in that users do not have to learn complicated sparse matrix data structures. Instead, *hypre* does the work of building these data structures for the user through a variety of interfaces, each appropriate to different classes of users. These include stencil-based structured/semi-structured interfaces most appropriate for finite-difference applications; a finite-element based unstructured interface; and a linear-algebra based interface. Each interface provides access to several solvers without the need to write new interface code.

- **User options accommodate beginners through experts**: *hypre* allows a spectrum of expertise to be applied by users. The beginning user can get up and running with a minimal
amount of effort. More expert users can take further control of the solution process through various parameters.

- **Configuration options to suit your computing system:** *hype* utilizes the GNU Autoconf package to allow simple and flexible installation on a wide variety of computing systems. Users can tailor the installation to match their computing system. Options include debug and optimized modes, the ability to change required libraries such as MPI and BLAS, a sequential mode, and modes enabling threads for certain solvers. On most systems, however, *hype* can be built by simply typing `configure` followed by `make`.

- **Interfaces in multiple languages provide greater flexibility for applications:** *hype* contains interfaces for both Fortran and C users.

## 1.2 Assumptions and Limitations

- *hype* is designed for large, sparse, linear systems on parallel computers. Small linear systems, systems that are solvable on a sequential computer, and dense systems are all better addressed by other libraries that are designed specifically for them.

- To run in parallel, *hype* requires an installation of MPI.

- Configuration of *hype* with threads requires an implementation of OpenMP. Currently, only a subset of *hype* is threaded.

- *hype* currently does not support complex-valued systems.
Chapter 2

Getting Started

Before writing any code:

1. **Choose a conceptual interface** (see Sections 2.2 and 2.3). Generally, the choice is fairly obvious. A structured-grid interface is clearly inappropriate for an unstructured-grid application. It is desirable to use a more specific interface if appropriate, e.g., the linear-algebraic interface is usable from any type of grid but will involve much more user work and prevent access to some grid-type-specific preconditioners.

2. **Choose your desired solver strategy.** For the typical user, this will mean a single Krylov method and a single preconditioner.

3. **Look up matrix requirements for each solver and preconditioner.** Each specific solver and preconditioner has requirements from the input matrix. This information is provided in several places: Chapter 7, the hypre Reference Manual, and the hypre header files.

4. **Choose a matrix class that is compatible with your solvers and preconditioners and your conceptual interface.** Note that some of the interfaces currently only support one matrix class choice.

Once the previous decisions have been made, it is time to code your application to call hypre:

1. **Build any necessary auxiliary structures for your chosen conceptual interface.** This includes, e.g., the grid and stencil structures for the structured-grid interface.

2. **Build the matrix, solution vector, and right-hand-side vector through your chosen conceptual interface.** Each conceptual interface provides a series of calls for entering information about your problem into hypre.

3. **Build solvers and preconditioners and set solver parameters (optional).** Some parameters like convergence tolerance are the same across solvers, while others are solver specific.
4. Call the solve function for the solver.

5. **Retrieve desired information from solver.** Depending on your application, there may be different things you may want to do with the solution vector. Also, performance information such as number of iterations is typically available, though it may differ from solver to solver.

### 2.1 A Simple Example

The following code serves as a simple example of the usage of *hypre*. In this example, the structured-grid interface (discussed in Chapter 3) is used to enter the problem into *hypre*, and the PFMG Multigrid solver is used to solve the system. Since the structured-grid interface currently only supports one underlying matrix class, there are no choices to make here. If we were using the semi-structured grid interface instead, then we would have to choose between the SStruct and ParCSR matrix classes, depending on the solver we want to use.

This example and all other examples in this manual are written in C, but *hypre* also supports Fortran. See Section 8.2 for details.

```c
/* -----------------------------------------------*/
* Set up the grid and stencil
* -----------------------------------------------*/
HYPRE_StructGridCreate(MPI_COMM_WORLD, dim, &grid);
HYPRE_StructGridSetExtents(grid, ilower, iupper);
...
HYPRE_StructGridAssemble(grid);

HYPRE_StructStencilCreate(dim, stencil_size, &stencil);
HYPRE_StructStencilSetElement(stencil, 0, offset0);
...

/* -----------------------------------------------*/
* Set up the matrix, right-hand side, and initial guess
* -----------------------------------------------*/
HYPRE_StructMatrixCreate(MPI_COMM_WORLD, grid, stencil, &A);
HYPRE_StructMatrixInitialize(A);
HYPRE_StructMatrixSetBoxValues(A, ilower, iupper, nelts, elts, Avalues);
...
HYPRE_StructMatrixAssemble(A);

HYPRE_StructVectorCreate(MPI_COMM_WORLD, grid, &b);
HYPRE_StructVectorInitialize(b);
```
HYPRE_StructVectorSetBoxValues(b, ilower, iupper, bvalues);
...
HYPRE_StructVectorAssemble(b);

HYPRE_StructVectorCreate(MPI_COMM_WORLD, grid, &x);
HYPRE_StructVectorInitialize(x);
HYPRE_StructVectorSetBoxValues(x, ilower, iupper, xvalues);
...
HYPRE_StructVectorAssemble(x);

/*/-------------------------------------------------------------
 * Set up the solver
 *-------------------------------------------------------------*/

HYPRE_StructPFMGCreate(MPI_COMM_WORLD, &solver);
HYPRE_StructPFMGSetMaxIter(solver, 50); /* optional */
HYPRE_StructPFMGSetTol(solver, 1.0e-06); /* optional */
HYPRE_StructPFMGsetup(solver, A, b, x);

/*/-------------------------------------------------------------
 * Solve the linear system
 *-------------------------------------------------------------*/

HYPRE_StructPFMGsolve(solver, A, b, x);

/*/-------------------------------------------------------------
 * Get solution info and free up memory
 *-------------------------------------------------------------*/

HYPRE_StructVectorGetBoxValues(x, ilower, iupper, xvalues);
...

HYPRE_StructPFMGDestroy(solver);
HYPRE_StructGridDestroy(grid);
HYPRE_StructStencilDestroy(stencil);
HYPRE_StructMatrixDestroy(A);
HYPRE_StructVectorDestroy(b);
HYPRE_StructVectorDestroy(x);
2.2 What are conceptual interfaces?

The top row of Figure 2.1 illustrates a number of conceptual interfaces. Generally, the conceptual interfaces are denoted by different types of computational grids, but other application features might also be used, such as geometrical information. These conceptual interfaces are intended to represent the way that applications developers naturally think of their linear problem, and provide natural interfaces for them to pass the data that defines their linear system into *hypre*. Essentially, these conceptual interfaces can be considered convenient utilities for helping a user build a matrix data structure for *hypre* solvers and preconditioners. For example, applications that use structured grids (such as in the left-most interface in the Figure 2.1) typically view their linear problems in terms of stencils and grids. On the other hand, applications that use unstructured grids and finite elements typically view their linear problems in terms of elements and element stiffness matrices. Finally, the right-most interface is the standard linear-algebraic (matrix rows/columns) way of viewing the linear problem.

The second row of Figure 2.1 is a set of linear solver algorithms. Each linear solver group requires different information from the user through the conceptual interfaces. So, the geometric multigrid algorithm (GMG) listed in the left-most box, for example, can only be used with the left-most conceptual interface. On the other hand, the ILU algorithm in the right-most box may be used with any conceptual interface.

The third row of Figure 2.1 is a list of data layouts or matrix/vector storage schemes. The relationship between linear solver and storage scheme is similar to that of interface and linear solver.
2.3 Which conceptual interface should I use?

Hypre currently supports four conceptual interfaces:

- **Structured-Grid System Interface (Struct):** This interface is appropriate for applications whose grids consist of unions of logically rectangular grids with a fixed stencil pattern of nonzeros at each grid point. This interface supports only a single unknown per grid point. See Chapter 3 for details.

- **Semi-Structured-Grid System Interface (SStruct):** This interface is appropriate for applications whose grids are mostly structured, but with some unstructured features. Examples include block-structured grids, composite grids in structured adaptive mesh refinement (AMR) applications, and overset grids. This interface supports multiple unknowns per cell. See Chapter 4 for details. **NOTE:** This is a somewhat new interface and should be used with caution as it matures.

- **Finite Element Interface (FEI):** This is appropriate for users who form their linear systems from a finite element discretization. The interface mirrors typical finite element data structures, including element stiffness matrices. Though this interface is provided in Hypre, its definition was determined elsewhere (www.z.ca.sandia.gov/fei). See Chapter 5 for details.

- **Linear-Algebraic System Interface (IJ):** This is the traditional linear-algebraic interface. It can be used as a last resort by users for whom the other grid-based interfaces are not appropriate. It requires more work on the user's part, though still less than building parallel sparse data structures. General solvers and preconditioners are available through this interface, but not specialized solvers which need more information. Our experience is that users with legacy codes, in which they already have code for building matrices in particular formats, find the IJ interface relatively easy to use. See Chapter 6 for details.

Generally, a user should choose the most specific interface that matches their application, because this will allow them to use specialized and more efficient solvers and preconditioners without losing access to more general solvers.
Chapter 3

Structured-Grid System Interface (Struct)

In order to get access to the most efficient and scalable solvers for scalar structured-grid applications, users should use the Struct interface described in this chapter. This interface will also provide access (this is not yet supported) to solvers in hypre that were designed for unstructured-grid applications and sparse linear systems in general. These additional solvers are usually provided via the unstructured-grid interface (FEI) or the linear-algebraic interface (IJ) described in Chapters 5 and 6.

Figure 3.1 gives an example of the type of grid currently supported by the Struct interface. The interface uses a finite-difference or finite-volume style, and currently supports only scalar PDEs (i.e., one unknown per gridpoint). There are four basic steps involved in setting up the linear system to be solved:

1. set up the grid,
2. set up the stencil,
3. set up the matrix,
4. set up the right-hand-side vector.

To describe each of these steps in more detail, consider solving the 2D Laplacian problem

\[ \begin{align*}
\nabla^2 u &= f, & \text{in the domain}, \\
    u &= 0, & \text{on the boundary}.
\end{align*} \tag{3.1} \]

Assume (3.1) is discretized using standard 5-pt finite-volumes on the uniform grid pictured in 3.1, and assume that the problem data is distributed across two processes as depicted.
3.1 Setting Up the Struct Grid

The grid is described via a global index space, i.e., via integer tuples (triples in 3D). The integers may have any value, negative or positive. The global indexes allow hypre to discern how data is related spatially, and how it is distributed across the parallel machine. Each process describes that portion of the grid that it “owns”, one box at a time. For example, in the figure, the global grid can be described in terms of three boxes, two owned by process 0, and one owned by process 1. A box is described in terms of a lower and upper index.

On process 0, the following code will set up the grid shown in the figure (the code for process 1 is similar).

```c
HYPRE_StructGrid grid;
int ilower[2][2] = {{-3, 1}, {0, 1}};
int iupper[2][2] = {{-1, 2}, {2, 4}};
HYPRE_StructGridCreate(MPI_COMM_WORLD, 2, &grid);

HYPRE_StructGridSetExtents(grid, ilower[0], iupper[0]);
HYPRE_StructGridSetExtents(grid, ilower[1], iupper[1]);

HYPRE_StructGridAssemble(grid);
```

The `Create()` routine creates an empty 2D grid object that lives on the `MPI_COMM_WORLD` communicator. The `SetExtents()` routine adds a new box to the grid. The `Assemble()` routine is a collective call (i.e., must be called on all processes from a common synchronization point), and finalizes the grid assembly, making the grid “ready to use”. 

Figure 3.1: An example 2D structured grid, distributed across two processors.
3.2 Setting Up the Struct Stencil

The geometry of the discretization stencil is described by an array of integer tuples in 2D (triples in 3D), each representing a relative offset (in index space) from some gridpoint on the grid. For example, the geometry of the 5-pt stencil for the example problem being considered can be represented in the following way:

\[
\begin{bmatrix}
-1, 0 \\
0, 0 \\
0, -1 \\
1, 0 \\
0, 1 \\
\end{bmatrix}
\equiv
\begin{bmatrix}
S_1 \\
S_0 \\
S_2 \\
S_3 \\
\end{bmatrix}.
\]

(3.2)

In (3.2), the (0, 0) entry represents the “center” coefficient, and is the 0th entry in the array (S_0). The (0, -1) entry represents the “south” coefficient, and is the 3rd entry in the array (S_3). And so on.

On process 0 or 1, the following code will set up the stencil in (3.2). The stencil must be the same on all processes.

```c
HYPRE_StructStencil stencil;
int offsets[5][2] = {{0, 0}, {-1, 0}, {1, 0}, {0, -1}, {0, 1}};
int s;
HYPRE_StructStencilCreate(2, 5, &stencil);

for (s = 0; s < 5; s++)
{
    HYPRE_StructStencilSetElement(stencil, s, offsets[s]);
}
```

The `Create()` routine creates an empty 2D, 5-pt stencil object. The `SetElement()` routine defines the geometry of the stencil and assigns the array numbers for each of the stencil entries. None of the calls are collective calls.

3.3 Setting Up the Struct Matrix

The matrix is set up in terms of the grid and stencil objects described in Sections 3.1 and 3.2. The coefficients associated with each stencil entry will typically vary from gridpoint to gridpoint, but in the example problem being considered, they are as follows over the entire grid (except at boundaries; see below):

\[
\begin{bmatrix}
-1 \\
-1 \\
4 \\
-1 \\
\end{bmatrix}.
\]

(3.3)
On process 0, the following code will set up matrix values associated with the center \((S_0)\) and south \((S_3)\) stencil entries in (3.2) / (3.3) (boundaries are ignored here temporarily).

```c
HYPRE_StructMatrix A;
double values[36];
int stencil_indices[2] = {0, 3};
int i;

HYPRE_StructMatrixCreate(MPI_COMM_WORLD, grid, stencil, &A);
HYPRE_StructMatrixInitialize(A);

for (i = 0; i < 36; i += 2)
{
    values[i] = 4.0;
    values[i+1] = -1.0;
}

HYPRE_StructMatrixSetBoxValues(A, ilower[0], iupper[0], 2,
                               stencil_indices, values);
HYPRE_StructMatrixSetBoxValues(A, ilower[1], iupper[1], 2,
                               stencil_indices, values);

/* set boundary conditions */
...

HYPRE_StructMatrixAssemble(A);
```

The `Create()` routine creates an empty matrix object. The `Initialize()` routine indicates that the matrix coefficients (or values) are ready to be set. This routine may or may not involve the allocation of memory for the coefficient data, depending on the implementation. The optional `Set` routines mentioned later in this chapter and in the Reference Manual, should be called before this step. The `SetBoxValues()` routine sets the matrix coefficients for some set of stencil entries over the gridpoints in some box. Note that the box need not correspond to any of the boxes used to create the grid, but values should be set for all gridpoints that this process “owns”. The `Assemble()` routine is a collective call, and finalizes the matrix assembly, making the matrix “ready to use”.

Matrix coefficients that reach outside of the boundary should be set to zero. For efficiency reasons, `hypre` does not do this automatically. The most natural time to insure this is when the boundary conditions are being set, and this is most naturally done after the coefficients on the grid’s interior have been set. For example, during the implementation of the Dirichlet boundary condition on the lower boundary of the grid in Figure 3.1, the “south” coefficient must be set to zero. To do this on process 0, the following code could be used:
int ilower[2] = {-3, 1};
int iupper[2] = {2, 1};

/* create matrix and set interior coefficients */
...

/* implement boundary conditions */
...

for (i = 0; i < 12; i++)
{
    values[i] = 0.0;
}

i = 3;
HYPRE_StructMatrixSetBoxValues(A, ilower, iupper, 1, &i, values);

/* complete implementation of boundary conditions */
...

3.4 Setting Up the Struct Right-Hand-Side Vector

The right-hand-side vector is set up similarly to the matrix set up described in Section 3.3 above. The main difference is that there is no stencil (note that a stencil currently does appear in the interface, but this will eventually be removed).

On process 0, the following code will set up the right-hand-side vector values.

HYPRE_StructVector b;
double values[18];
int i;

HYPRE_StructVectorCreate(MPI_COMM_WORLD, grid, &b);
HYPRE_StructVectorInitialize(b);

for (i = 0; i < 18; i++)
{
    values[i] = 0.0;
}

HYPRE_StructVectorSetBoxValues(b, ilower[0], iupper[0], values);
CHAPTER 3. STRUCTURED-GRID SYSTEM INTERFACE (STRUCT)

    HYPRE_StructVectorSetBoxValues(b, ilower[1], iupper[1], values);
    HYPRE_StructVectorAssemble(b);

The Create() routine creates an empty vector object. The Initialize() routine indicates that the vector coefficients (or values) are ready to be set. This routine follows the same rules as its corresponding Matrix routine. The SetBoxValues() routine sets the vector coefficients over the gridpoints in some box, and again, follows the same rules as its corresponding Matrix routine. The Assemble() routine is a collective call, and finalizes the vector assembly, making the vector “ready to use”.

3.5 Symmetric Matrices

Some solvers and matrix storage schemes provide capabilities for significantly reducing memory usage when the coefficient matrix is symmetric. In this situation, each off-diagonal coefficient appears twice in the matrix, but only one copy needs to be stored. The Struct interface provides support for matrix and solver implementations that use symmetric storage via the SetSymmetric() routine.

To describe this in more detail, consider again the 5-pt finite-volume discretization of (3.1) on the grid pictured in Figure 3.1. Because the discretization is symmetric, only half of the off-diagonal coefficients need to be stored. To turn symmetric storage on, the following line of code needs to be inserted somewhere between the Create() and Initialize() calls.

    HYPRE_StructMatrixSetSymmetric(A, 1);

Note that symmetric storage may or may not actually be used, depending on the underlying storage scheme. Currently in hypre, symmetric storage is always used when indicated.

To most efficiently utilize the Struct interface for symmetric matrices, notice that only half of the off-diagonal coefficients need to be set. To do this for the example being considered, we simply need to redefine the 5-pt stencil of Section 3.2 to an “appropriate” 3-pt stencil, then set matrix coefficients (as in Section 3.3) for these three stencil elements only. For example, we could use the following stencil

\[
\begin{bmatrix}
(0,1) \\
(0,0) \\
(1,0)
\end{bmatrix}
= \begin{bmatrix}
S_2 \\
S_0 \\
S_1
\end{bmatrix}.
\]  

(3.4)

This 3-pt stencil provides enough information to recover the full 5-pt stencil geometry and associated matrix coefficients.
Chapter 4

Semi-Structured-Grid System Interface (SSStruct)

In order to get access to the most efficient and scalable solvers for semi-structured-grid applications (applications with grids that are mostly structured, but with some unstructured features), users should use the SSStruct interface described in this chapter. This interface also provides access to solvers in hypre that were designed for unstructured-grid applications and sparse linear systems in general. These additional solvers are usually provided via the unstructured-grid interface (FEI) or the linear-algebraic interface (IJ) described in Chapters 5 and 6.

Figure 4.1 gives an example of the type of grid currently supported by the SSStruct interface. The grid is composed of three “parts”. There is a single cell-centered variable across the entire grid, except at the grid cell marked with a square, which has one additional cell-centered variable. There are five basic steps involved in setting up the linear system to be solved:

1. set up the grid,
2. set up the stencils,
3. set up the graph,
4. set up the matrix,
5. set up the right-hand-side vector.

To describe each of these steps in more detail, consider solving the 2D Laplacian problem

\[
\begin{align*}
\nabla^2 u &= f, \quad \text{in the domain,} \\
 u &= 0, \quad \text{on the boundary.}
\end{align*}
\]

(4.1)

Assume (3.1) is discretized using standard 9-pt finite-volumes on the grid pictured in 4.1, and assume that the problem data is distributed across three processes as depicted. In the figure, each grid part is distributed onto a different process, but this need not be the case; each grid part may also be distributed across several processes. Assume for simplicity and illustration that there is a
single coupling between the first and second variables in grid part 0 at index (1,2). In general, this variable may also be coupled to variables at neighboring indices.

### 4.1 Setting Up the SStruct Grid

On process 0, the following code will set up the grid shown in the figure (the code for processes 1 and 2 is similar).

```c
HYPRE_SStructGrid grid;
int ilower[2][2] = {{-1, 0}, {1, 0}};
int iupper[2][2] = {{ 0, 3}, {2, 3}};
HYPRE_SStructVariable vars[1] = {HYPRE_SSTRUCT_VARIABLE_CELL};

int addindex[2] = {1,2};
HYPRE_SStructVariable addvars[1] = {HYPRE_SSTRUCT_VARIABLE_CELL};

HYPRE_SStructGridCreate(MPI_COMM_WORLD, 2, 3, &grid);

HYPRE_SStructGridSetExtents(grid, 0, ilower[0], iupper[0]);
```
The Create() routine creates an empty 2D grid object that lives on the MPI_COMM_WORLD communicator. The SetExtents() routine adds a new box to the grid. The SetVariables() routine sets the variables on a grid part, and the AddVariables() routine adds variables to a grid part index (in the above example, there are two cell-centered variables at index (1,2)). The Assemble() routine is a collective call (i.e., must be called on all processes from a common synchronization point), and finalizes the grid assembly, making the grid “ready to use”.

4.2 Setting Up the SStruct Stencil

The geometry of the discretization stencil is described by an array of integer tuples in 2D (triples in 3D), each representing a relative offset (in index space) from some gridpoint on the grid. For example, the geometry of the 9-pt stencil for the example problem being considered can be represented in the following way:

\[
\begin{bmatrix}
(-1,1) & (0,1) & (1,1) \\
(-1,0) & (0,0) & (1,0) \\
(-1,-1) & (0,-1) & (1,-1)
\end{bmatrix} \equiv
\begin{bmatrix}
S_7 & S_4 & S_8 \\
S_1 & S_0 & S_2 \\
S_5 & S_3 & S_6
\end{bmatrix}.
\] (4.2)

In (4.2), the (0,0) entry represents the “center” coefficient, and is the 0th entry in the array \(S_0\). The (0,-1) entry represents the “south” coefficient, and is the 3rd entry in the array \(S_3\). And so on.

On process 0, 1, or 2, the following code will set up the stencil in (4.2).

```c
HYPRE_SStructStencil stencil;
int s;
int offsets[9][2] = {{0,0},
                    {1,0}, {0,-1}, {0,1},
                    {-1,0}, {-1,-1}, {-1,1}, {1,1}};

HYPRE_SStructStencilCreate(2, 9, &stencil);

for (s = 0; s < 9; s++)
    HYPRE_SStructStencilSetEntry(stencil, s, offsets[s], 0);
```
The `Create()` routine creates an empty 2D, 9-pt stencil object. The `SetEntry()` routine defines the geometry of the stencil, and assigns the array numbers for each of the stencil entries. None of the calls are collective calls.

### 4.3 Setting Up the SStruct Graph

The graph will represent the nonzero structure of the matrix in Section 4.4 below. It is defined in terms of the grid and stencil objects described in Sections 4.1 and 4.2 above.

On process 0, the following code will set up the graph for the example problem.

```c
HYPRE_SStructGraph graph;
int addindex[9][2] = {{ 2,0},{2,1},{2,2},{2,3},
               {-1,3},{0,3},{1,3},{2,3},
               { 1,2}};
int addentries[9][2] = {{-1,0},{-1,1},{-1,2},{-1,3},
               { 9,9},{10,9},{11,9},{12,9},
               { 1,2}};

HYPRE_SStructGraphCreate(MPI_COMM_WORLD, grid, &graph);
HYPRE_SStructGraphSetStencil(graph, 0, 0, stencil);

/* Add graph edge entries at grid part boundaries */
HYPRE_SStructGraphAddEntries(graph, 0, addindex[0], 0, 2, addentries[0], 0);
HYPRE_SStructGraphAddEntries(graph, 0, addindex[0], 0, 2, addentries[1], 0);
HYPRE_SStructGraphAddEntries(graph, 0, addindex[1], 0, 2, addentries[0], 0);
...

/* Add graph edge entries at index (1,2) */
HYPRE_SStructGraphAddEntries(graph, 0, addindex[8], 0, 0, addentries[8], 1);
HYPRE_SStructGraphAddEntries(graph, 0, addindex[8], 1, 0, addentries[8], 0);
```

### 4.4 Setting Up the SStruct Matrix

The matrix is set up in terms of the graph object described in Section 4.3 above. The coefficients associated with each graph entry will typically vary from gridpoint to gridpoint, but in the example problem being considered, they are as follows over the entire grid (except at boundaries; see below):

\[
\begin{bmatrix}
-1 & -1 & -1 \\
-1 & 8 & -1 \\
-1 & -1 & -1
\end{bmatrix}
\] (4.3)
4.4. SETTING UP THE SSTRUCT MATRIX

On process 0, the following code will set up matrix values associated with the center ($S_0$) and south ($S_3$) stencil entries in (3.2) / (3.3). Matrix values associated with the non-stencil graph entries are also set up.

```c
HYPRE_SStructMatrix A;
double values[32];
int sindices[2] = {0, 3};
int gindices[4] = {9, 10, 11, 0};
int i;

HYPRE_SStructMatrixCreate(MPI_COMM_WORLD, graph, &A);
HYPRE_SStructMatrixInitialize(A);

for (i = 0; i < 32; i += 2)
{
    values[i] = 8.0;
    values[i+1] = -1.0;
}
HYPRE_SStructMatrixSetBoxValues(A, 0, ilower[0], iupper[0], 0, 2, sindices, values);

/* set values at non-stencil graph entries */
for (i = 0; i < 3; i++)
{
    values[i] = -1.0;
}
HYPRE_SStructMatrixSetValues(A, 0, addindex[0], 0, 2, gindices, values);
HYPRE_SStructMatrixSetValues(A, 0, addindex[1], 0, 3, gindices, values);
HYPRE_SStructMatrixSetValues(A, 0, addindex[2], 0, 3, gindices, values);
...  
HYPRE_SStructMatrixSetValues(A, 0, addindex[7], 0, 1, gindices, values);
HYPRE_SStructMatrixSetValues(A, 0, addindex[7], 1, 1, &gindices[3], values);

/* zero out coefficients that reach outside of the domain or grid part */
...

/* set boundary conditions at domain boundaries */
...

HYPRE_SStructMatrixAssemble(A);
```
4.5 Setting Up the SStruct Right-Hand-Side Vector

The right-hand-side vector is set up similarly to the matrix set up described in Section 4.4 above. The main difference is that there is no graph.
Chapter 5

Finite Element Interface (FEI)

The finite element interface (FEI) defines a linear solver interface for finite element applications. For information on how to use this interface, see [4]. This chapter describes the iterative methods and preconditioners in the hypre implementation of this interface.

Solving a linear system from a finite element problem consists of four steps in the FEI:

1. Initialize the structure of the finite-element data, including loading the element connectivity data
2. Load the element or super-element stiffness matrices and forcing terms
3. Set solver parameters and solve the linear system
4. Retrieve the solution to the linear system

Parameters to the hypre solvers are specified by calling

```c
void FEI_parameters(int sysHandle, int numParams, char **paramStrings);
```

where `sysHandle` is an identifier for the linear system being solved, `numParams` is the number of parameter strings, and `paramStrings` is an array of null-terminated strings with the format: "parameter_name value". For example, setting the preconditioner can be accomplished by:

```c
char **paramStrings[1];
paramStrings[0] = (char *) malloc(64*sizeof(char));
strcpy(paramStrings[0], "preconditioner parasails");
FEI_parameters(sysHandle, 1, paramStrings);
```

All possible parameters are listed in Table 5.1.
A linear system is then solved by calling

```c
void FEI_iterateToSolve(int sysHandle);
```
5.1 Iterative methods and preconditioners available

5.1.1 Iterative methods

1. Krylov solvers (conjugate gradient, GMRES, TFQMR, BiCGSTAB)
2. BoomerAMG (a parallel algebraic multigrid solver)
3. SuperLU direct solver (sequential)
4. SuperLU direct solver with iterative refinement (sequential)

5.1.2 Preconditioners

1. diagonal
2. parallel incomplete LU with threshold (PILUT)
3. another parallel incomplete LU (Euclid)
4. parallel algebraic multigrid (BoomerAMG)
5. parallel sparse approximate inverse (ParaSails)
<table>

Chapter 6

Linear-Algebraic System Interface (IJ)

The IJ interface described in this chapter is the lowest common denominator for specifying linear systems in hypre. This interface provides access to general sparse-matrix solvers in hypre, not to the specialized solvers that require more problem information.

6.1 IJ Matrix Interface

As with the other interfaces in hypre, the IJ interface expects to get data in distributed form because this is the only scalable approach for assembling matrices on thousands of processes. Matrices are assumed to be distributed by blocks of rows as follows:

\[
\begin{bmatrix}
A_0 \\
A_1 \\
\vdots \\
A_{P-1}
\end{bmatrix}
\]  

(6.1)

In the above example, the matrix is distributed across the \( P \) processes, 0, 1, ..., \( P - 1 \) by blocks of rows. Each submatrix \( A_p \) is “owned” by a single process and its first and last row numbers are given by the global indices \( i_{lower} \) and \( i_{upper} \) in the \texttt{Create()} call below.

The following example code illustrates the basic usage of the IJ interface for building matrices:

\begin{verbatim}
MPI_Comm comm;
HYPRE_IJMatrix ij_matrix;
HYPRE_ParCSRMatrix parcsr_matrix;
int ilower, iupper;
int jlower, jupper;
int nrows;
\end{verbatim}
int *ncols;
int *rows;
int *cols;
double *values;

HYPRE_IJMatrixCreate(comm, ilower, iupper, jlower, jupper, &ij_matrix);
HYPRE_IJMatrixSetObjectType(ij_matrix, HYPRE_PARCSR);
HYPRE_IJMatrixInitialize(ij_matrix);

/* set matrix coefficients */
HYPRE_IJMatrixSetValues(ij_matrix, nrows, ncols, rows, cols, values);
...
/* add-to matrix coefficients, if desired */
HYPRE_IJMatrixAddToValues(ij_matrix, nrows, ncols, rows, cols, values);
...

HYPRE_IJMatrixAssemble(ij_matrix);
HYPRE_IJMatrixGetObject(ij_matrix, (void **) &parcsr_matrix);

The Create() routine creates an empty matrix object that lives on the comm communicator. This is a collective call (i.e., must be called on all processes from a common synchronization point), with each process passing its own row extents, ilower and iupper. The row partitioning must be contiguous, i.e., iupper for process i must equal ilower − 1 for process i + 1. Note that this allows matrices to have 0- or 1-based indexing. The parameters jlower and jupper define a column partitioning, and should match ilower and iupper when solving square linear systems. See the Reference Manual for more information.

The SetObjectType() routine sets the underlying matrix object type to HYPRE_PARCSR (this is the only object type currently supported). The Initialize() routine indicates that the matrix coefficients (or values) are ready to be set. This routine may or may not involve the allocation of memory for the coefficient data, depending on the implementation. The optional SetRowSizes() and SetDiagOffdSizes() routines mentioned later in this chapter and in the Reference Manual, should be called before this step.

The SetValues() routine sets matrix values for some number of rows (nrows) and some number of columns in each row (ncols). The actual row and column numbers of the matrix values to be set are given by rows and cols. After the coefficients are set, they can be added to with an AddTo() routine. Each process should set only those matrix values that it “owns” in the data distribution.

The Assemble() routine is a collective call, and finalizes the matrix assembly, making the matrix “ready to use”. The GetObject() routine retrieves the built matrix object so that it can be passed on to hypre solvers that use the ParCSR internal storage format. Note that this is not an expensive routine; the matrix already exists in ParCSR storage format, and the routine simply returns a “handle” or pointer to it. Although we currently only support one underlying data storage format, in the future several different formats may be supported.
6.2. IJ VECTOR INTERFACE

One can preset the row sizes of the matrix in order to reduce the execution time for the matrix specification. One can specify the total number of coefficients for each row, the number of coefficients in the row that couple the diagonal unknown to (Diag) unknowns in the same processor domain, and the number of coefficients in the row that couple the diagonal unknown to (Offd) unknowns in other processor domains:

HYPRE_IJMatrixSetRowSizes(ij_matrix, sizes);
HYPRE_IJMatrixSetDiagOffdSizes(matrix, diag_sizes, offdiag_sizes);

Once the matrix has been assembled, the sparsity pattern cannot be altered without completely destroying the matrix object and starting from scratch. However, one can modify the matrix values of an already assembled matrix. To do this, first call the Initialize() routine to re-initialize the matrix, then set or add-to values as before, and call the Assemble() routine to re-assemble before using the matrix. Re-initialization and re-assembly are very cheap, essentially a no-op in the current implementation of the code.

6.2 IJ Vector Interface

The following example code illustrates the basic usage of the IJ interface for building vectors:

MPI_Comm comm;
HYPRE_IJVector ij_vector;
HYPRE_ParVector par_vector;
int jlower, jupper;
int nvalues;
int *indices;
double *values;

HYPRE_IJVectorCreate(comm, jlower, jupper, &ij_vector);
HYPRE_IJVectorSetObjectType(ij_vector, HYPRE_PARCSR);
HYPRE_IJVectorInitialize(ij_vector);

/* set vector values */
HYPRE_IJVectorSetValues(ij_vector, nvalues, indices, values);
...

HYPRE_IJVectorAssemble(ij_vector);
HYPRE_IJVectorGetObject(ij_vector, (void **) &par_vector);

The Create() routine creates an empty vector object that lives on the comm communicator. This is a collective call, with each process passing its own index extents, jlower and jupper. The names
of these extent parameters begin with a \( j \) because we typically think of matrix-vector multiplies as the fundamental operation involving both matrices and vectors. For matrix-vector multiplies, the vector partitioning should match the column partitioning of the matrix (which also uses the \( j \) notation). For linear system solves, these extents will typically match the row partitioning of the matrix as well.

The `SetObjectType()` routine sets the underlying vector storage type to `HYPRE_PARCSR` (this is the only storage type currently supported). The `Initialize()` routine indicates that the vector coefficients (or values) are ready to be set. This routine may or may not involve the allocation of memory for the coefficient data, depending on the implementation.

The `SetValues()` routine sets the vector values for some number (`nvalues`) of indices. Each process should set only those vector values that it “owns” in the data distribution.

The `Assemble()` routine is a trivial collective call, and finalizes the vector assembly, making the vector “ready to use”. The `GetObject()` routine retrieves the built vector object so that it can be passed on to `hypre` solvers that use the `ParVector` internal storage format.

Vector values can be modified in much the same way as with matrices by first re-initializing the vector with the `Initialize()` routine.
Chapter 7

Solvers and Preconditioners

There are several solvers available in hmpre via different conceptual interfaces (see Table 7.1). The procedure for setup and use of solvers and preconditioners is largely the same. We will refer to them both as solvers in the sequel except when noted. In normal usage, the preconditioner is chosen and constructed before the solver, and then handed to the solver as part of the solver’s setup. In the following, we assume the most common usage pattern in which a single linear system is set up and then solved with a single righthand side. We comment later on considerations for other usage patterns.

Table 7.1: Current solver availability via hmpre conceptual interfaces.

Setup:

1. **Pass to the solver the information defining the problem.** In the typical user cycle, the user has passed this information into a matrix through one of the conceptual interfaces prior to setting up the solver. In this situation, the problem definition information is then passed to the solver by passing the constructed matrix into the solver. As described before, the
matrix and solver must be compatible, in that the matrix must provide the services needed by the solver. Krylov solvers, for example, need only a matrix-vector multiplication. Most preconditioners, on the other hand, have additional requirements such as access to the matrix coefficients.

2. **Choose parameters for the preconditioner and/or solver.** Parameters are chosen through the Set() calls provided by the solver. As is true throughout hypre, all parameters have reasonable defaults if not chosen. Note that in hypre, convergence criteria can be chosen after the preconditioner/solver has been setup.

3. **Pass the preconditioner to the solver.** For solvers that are not preconditioned, this step is omitted. The preconditioner is passed through the SetPreconditioner() call.

4. **Set up the solver.** This is just the Setup() routine.

At this point, the solver/preconditioner is fully constructed and ready for use.

**Use:**

1. **Set convergence criteria.** Convergence can be controlled by the number of iterations, as well as various tolerances such as relative residual, preconditioned residual, etc. Like all parameters, reasonable defaults are used. Users are free to change these, though care must be taken. For example, if an iterative method is used as a preconditioner for a Krylov method, a constant number of iterations is usually required.

2. **Solve the system.** This is just the Solve() routine.

## 7.1 SMG

SMG is a parallel semicoarsening multigrid solver for the linear systems arising from finite difference, finite volume, or finite element discretizations of the diffusion equation,

\[ \nabla \cdot (D \nabla u) + \sigma u = f \]  \hspace{1cm} (7.1)

on logically rectangular grids. The code solves both 2D and 3D problems with discretization stencils of up to 9-point in 2D and up to 27-point in 3D. See [10, 2, 5] for details on the algorithm and its parallel implementation/performance.

SMG is a particularly robust method. The algorithm semicoarsens in the z-direction and uses plane smoothing. The xy plane-solves are effected by one V-cycle of the 2D SMG algorithm, which semicoarsens in the y-direction and uses line smoothing.
7.2 PFMG

PFMG is a parallel semicoarsening multigrid solver similar to SMG. See [1, 5] for details on the algorithm and its parallel implementation/performance.

The main difference between the two methods is in the smoother: PFMG uses simple pointwise smoothing. As a result, PFMG is not as robust as SMG, but is much more efficient per V-cycle.

7.3 BoomerAMG

BoomerAMG is a parallel implementation of algebraic multigrid. It can be used both as a solver or as a preconditioner. The user can choose between various different parallel coarsening techniques and relaxation schemes. See [6] for a detailed description of the coarsening algorithms, the interpolation and mecemrical results. The following coarsening techniques are available:

- the Cleary-Luby-Jones-Plassman (CLJP) coarsening,
- various variants of the classical Ruge-Stueben (RS) coarsening algorithm, and
- the Falgout coarsening which is a combination of CLJP and the classical RS coarsening algorithm.

The following relaxation techniques are available:

- weighted Jacobi relaxation,
- a hybrid Gauss-Seidel / Jacobi relaxation scheme,
- a symmetric hybrid Gauss-Seidel / Jacobi relaxation scheme, and
- sequential Gauss-Seidel relaxation.

7.3.1 Synopsis

The solver is set up and run using the following routines, where A is the matrix, b the right hand side and x the solution vector of the linear system to be solved:

```c
#include "HYPRE_parcsr_ls.h"

int HYPRE_BoomerAMGCreate(HYPRE_Solver *solver);

<set certain parameters if desired >

int HYPRE_BoomerAMGSetup(HYPRE_Solver solver, HYPRE_ParCSRMatrix A,
                        HYPRE_ParVector b, HYPRE_ParVector x);
int HYPRE_BoomerAMGSolve(HYPRE_Solver solver, HYPRE_ParCSRMatrix A,
                        HYPRE_ParVector b, HYPRE_ParVector x);
int HYPRE_BoomerAMGDestroy(HYPRE_Solver solver);
```
7.3.2 Interface functions
Parameters for setting up the code are specified using the following routines:

**HYPER_BoomerAMGSetMaxLevels**

```c
int HYPRE_BoomerAMGSetMaxLevels( HYPRE_Solver solver, int max_levels);
```

max_levels defines the maximal number of multigrid levels allowed. The default is 25.

**HYPRE_BoomerAMGSetMaxIter**

```c
int HYPRE_BoomerAMGSetMaxIter( HYPRE_Solver solver, int max_iter);
```

max_iter defines the maximal number of iterations allowed. The default is 20.

**HYPRE_BoomerAMGSetTol**

```c
int HYPRE_BoomerAMGSetTol( HYPRE_Solver solver, double tol);
```

tol defines the tolerance needed for the stopping criterion $\| b - Ax^{(n)} \|_2 / \| b \|_2 \leq tol$. The default for tol is $10^{-7}$.

**HYPRE_BoomerAMGSetStrongThreshold**

```c
int HYPRE_BoomerAMGSetStrongThreshold( HYPRE_Solver solver, double strong_threshold);
```

A point $i$ is strongly connected to $j$, if $-a_{i,j} \geq \theta \max_{j \neq i} a_{ij}$, where the strong threshold $\theta$ is a value between 0 and 1. Weak connections are usually ignored when determining the next lower level. Consequently, choosing a larger strong threshold leads in general to smaller coarse grids, but worse convergence rates. The default value for $\theta$ is 0.25, which appears to be a good choice for 2-dimensional problems. A better choice for 3-dimensional problems appears to be 0.5. However, the choice of the strength threshold is problem dependent and therefore there could be better choices than the two suggested ones.

**HYPRE_BoomerAMGSetMaxRowSum**

```c
int HYPRE_BoomerAMGSetMaxRowSum( HYPRE_Solver solver, double max_row_sum);
```

This feature leads to a more efficient treatment of very diagonally dominant portions of the matrix. If the absolute row sum of row i weighted by the diagonal is greater than max_row_sum all dependencies of variable i are set to be weak. This feature can be switched off by setting max_row_sum to 1.0. The default is 0.9.
7.3. BOOMERAMG

**HYPRE_BoomerAMGSetCoarsenType**

```c
int HYPRE_BoomerAMGSetCoarsenType( HYPRE_Solver solver, int coarsen_type );
```

coarsen_type defines the coarsening used. The following options are possible:

0  CLJP-coarsening
1  Ruge-Stueben coarsening without boundary treatment
3  Ruge-Stueben coarsening with a 3rd 'second' pass on the boundaries
6  Falgout coarsening (default)

**HYPRE_BoomerAMGSetMeasureType**

```c
int HYPRE_BoomerAMGSetMeasureType( HYPRE_Solver solver, int measure_type );
```

measure_type defines whether local (measure_type = 0, default) or global measures (measure_type = 1) are used within the coarsening algorithm. This feature is ignored for the CLJP and the Falgout coarsening.

**HYPRE_BoomerAMGSetNumGridSweeps**

```c
int HYPRE_BoomerAMGSetNumGridSweeps( HYPRE_Solver solver, int* num_grid_sweeps );
```

num_grid_sweeps[k] defines the number of sweeps over the grid on the fine grid (k=0), the down cycle (k=1), the up cycle (k=2) and the coarse grid (k=3).

**HYPRE_BoomerAMGSetGridRelaxType**

```c
int HYPRE_BoomerAMGSetGridRelaxType( HYPRE_Solver solver, int* grid_relax_type );
```

grid_relax_type[k] defines the relaxation used on the fine grid (k=0), the down cycle (k=1), the up cycle (k=2) and the coarse grid (k=3). The following options are possible for grid_relax_type[k]:

0  weighted Jacobi
1  sequential Gauss-Seidel (very slow!)
3  Gauss-Seidel / Jacobi hybrid method (default)
6  symmetric Gauss-Seidel / Jacobi hybrid method
9  Gaussian elimination (only for the coarsest level (k=3), not recommended if the system on the coarsest level is large)

**HYPRE_BoomerAMGSetGridRelaxPoints**

```c
int HYPRE_BoomerAMGSetGridRelaxPoints( HYPRE_Solver solver, int** grid_relax_points );
```

grid_relax_points[i][j] defines which points are to be relaxed during the (j+1)-th sweep on the fine grid (i=0), the down cycle (i=1), the up cycle (i=2) and the coarse grid (i=3), e.g. if
grid.relax_points[1][0] is -1, all points marked -1 (which are in general fine points) are relaxed on the first sweep of the down cycle. Note: grid.relax_points[3][i] needs to be 0 always, since the concept of coarse and fine points does not exist on the coarsest grid. If the user sets it to another value, it will be automatically set to 0 and a warning printed, unless the direct solver is used.

**HYPRE_BoomerAMGSetRelaxWeight**

```c
int HYPRE_BoomerAMGSetRelaxWeight( HYPRE_Solver solver, double* relax_weight);
```

defines the relaxation weights used on each level, if weighted Jacobi is used as relaxation method. The default relaxation weight is 1.0 on each level.

**HYPRE_BoomerAMGSetIOutDat**

```c
int HYPRE_BoomerAMGSetIOutDat( HYPRE_Solver solver, int ioutdat);
```

where ioutdat determines whether statistics information is generated and printed. The information is printed to standard output. The following options are possible:

0 no output (default)
1 matrix statistics (includes information on interpolation operators and matrices generated on each level)
2 cycle statistics (includes residuals generated during solve phase)
3 matrix and cycle statistics

### 7.4 ParaSails

ParaSails is a parallel implementation of a sparse approximate inverse preconditioner, using a priori sparsity patterns and least-squares (Frobenius norm) minimization. Symmetric positive definite (SPD) problems are handled using a factored SPD sparse approximate inverse. General (nonsymmetric and/or indefinite) problems are handled with an unfactored sparse approximate inverse. It is also possible to precondition nonsymmetric but definite matrices with a factored, SPD preconditioner.

ParaSails uses a priori sparsity patterns that are patterns of powers of sparsified matrices. ParaSails also uses a post-filtering technique to reduce the cost of applying the preconditioner. In advanced usage not described here, the pattern of the preconditioner can also be reused to generate preconditioners for different matrices in a sequence of linear solves.

For more details about the ParaSails algorithm, see [3].

#### 7.4.1 Synopsis

```c
#include "HYPRE_parcsr_ls.h"

int HYPRE_ParaSailsCreate(MPI_Comm comm, HYPRE_Solver *solver,
                          int symmetry);
```
7.4. PARASAILS

int HYPRE_ParaSailsSetParams(HYPRE_Solver solver, double thresh, int nlevel, double filter);
int HYPRE_ParaSailsSetup(HYPRE_Solver solver, HYPRE_ParCSRMatrix A, HYPRE_ParVector b, HYPRE_ParVector x);
int HYPRE_ParaSailsSolve(HYPRE_Solver solver, HYPRE_ParCSRMatrix A, HYPRE_ParVector b, HYPRE_ParVector x);
int HYPRE_ParaSailsStats(HYPRE_Solver solver);
int HYPRE_ParaSailsDestroy(HYPRE_Solver solver);

The accuracy and cost of ParaSails are parameterized by the real \(thresh\) and integer \(nlevels\) parameters, \(0 \leq thresh \leq 1, 0 \leq nlevels\). Lower values of \(thresh\) and higher values of \(nlevels\) lead to more accurate, but more expensive preconditioners. More accurate preconditioners are also more expensive per iteration. The default values are \(thresh = 0.1\) and \(nlevels = 1\). The parameters are set using HYPRE_ParaSailsSetParams.

Mathematically, given a symmetric matrix \(A\), the pattern of the approximate inverse is the pattern of \(A^m\) where \(A\) is a matrix that has been sparsified from \(A\). The sparsification is performed by dropping all entries in a symmetrically diagonally scaled \(A\) whose values are less than \(thresh\) in magnitude. The parameter \(nlevel\) is equivalent to \(m + 1\). Filtering is a post-thresholding procedure. For more details about the algorithm, see [3].

The storage required for the ParaSails preconditioner depends on the parameters \(thresh\) and \(nlevels\). The default parameters often produce a preconditioner that can be stored in less than the space required to store the original matrix. ParaSails does not need a large amount of intermediate storage in order to construct the preconditioner.

7.4.2 Interface functions

A ParaSails solver \(solver\) is returned with

int HYPRE_ParaSailsCreate(MPI_Comm comm, HYPRE_Solver *solver, int symmetry);

where \(comm\) is the MPI communicator.

The value of \(symmetry\) has the following meanings, to indicate the symmetry and definiteness of the problem, and to specify the type of preconditioner to construct:

<table>
<thead>
<tr>
<th>value</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>nonsymmetric and/or indefinite problem, and nonsymmetric preconditioner</td>
</tr>
<tr>
<td>1</td>
<td>SPD problem, and SPD (factored) preconditioner</td>
</tr>
<tr>
<td>2</td>
<td>nonsymmetric, definite problem, and SPD (factored) preconditioner</td>
</tr>
</tbody>
</table>

For more information about the final case, see section 7.4.3.

Parameters for setting up the preconditioner are specified using

int HYPRE_ParaSailsSetParams(HYPRE_Solver solver, double thresh, int nlevel, double filter);
The parameters are used to specify the sparsity pattern and filtering value (see above), and are described with suggested values as follows:

<table>
<thead>
<tr>
<th>parameter</th>
<th>type</th>
<th>range</th>
<th>sug. values</th>
<th>default</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>nlevel</td>
<td>integer</td>
<td>nlevel ≥ 0</td>
<td>0, 1, 2</td>
<td>1</td>
<td>( m = nlevel + 1 )</td>
</tr>
<tr>
<td>thresh</td>
<td>real</td>
<td>thresh ≥ 0</td>
<td>0, 0.1, 0.01</td>
<td>0.1</td>
<td>( \text{thresh} = \text{thresh} )  ( \text{thresh selected automatically} )</td>
</tr>
<tr>
<td></td>
<td></td>
<td>thresh &lt; 0</td>
<td>-0.75, -0.90</td>
<td>0.1</td>
<td>( \text{thresh selected automatically} )</td>
</tr>
<tr>
<td>filter</td>
<td>real</td>
<td>filter ≥ 0</td>
<td>0, 0.05, 0.001</td>
<td>0.05</td>
<td>( \text{filter value} = \text{filter} )</td>
</tr>
<tr>
<td></td>
<td></td>
<td>filter &lt; 0</td>
<td>-0.90</td>
<td>0.05</td>
<td>( \text{filter value selected automatically} )</td>
</tr>
</tbody>
</table>

When \( \text{thresh} < 0 \), then a threshold is selected such that \(-\text{thresh}\) represents the fraction of the nonzero elements that are dropped. For example, if \( \text{thresh} = -0.9 \) then \( A \) will contain approximately ten percent of the nonzeros in \( A \).

When \( \text{filter} < 0 \), then a filter value is selected such that \(-\text{filter}\) represents the fraction of the nonzero elements that are dropped. For example, if \( \text{filter} = -0.9 \) then approximately 90 percent of the entries in the computed approximate inverse are dropped.

### 7.4.3 Preconditioning nearly symmetric matrices

A nonsymmetric, but definite and nearly symmetric matrix \( A \) may be preconditioned with a symmetric preconditioner \( M \). Using a symmetric preconditioner has a few advantages, such as guaranteeing positive definiteness of the preconditioner, as well as being less expensive to construct.

The nonsymmetric matrix \( A \) must be definite, i.e., \((A + A^T)/2\) is SPD, and the \( a \text{ priori} \) sparsity pattern to be used must be symmetric. The latter may be guaranteed by 1) constructing the sparsity pattern with a symmetric matrix, or 2) if the matrix is structurally symmetric (has symmetric pattern), then thresholding to construct the pattern is not used (i.e., zero value of the \( \text{thresh} \) parameter is used).

### 7.5 Euclid

The Euclid library is a scalable implementation of the Parallel ILU algorithm that was presented at SC99 [7], and published in expanded form in the SIAM Journal on Scientific Computing [8]. By scalable we mean that the factorization (setup) and application (triangular solve) timings remain nearly constant when the global problem size is scaled in proportion to the number of processors. As with all ILU preconditioning methods, the number of iterations is expected to increase with global problem size.

Experimental results have shown that PILU preconditioning is in general more effective than Block Jacobi preconditioning for minimizing total solution time. For scaled problems, the relative advantage appears to increase as the number of processors is scaled upwards. Euclid may also be used to good advantage as a smoother within multigrid methods.
7.5. EUCLID

7.5.1 Synopsis

Euclid is best thought of as an “extensible ILU preconditioning framework.” Extensible means that Euclid can (and eventually will, time and contributing agencies permitting) support many variants of ILU($k$) and ILUT preconditioning. (The current release includes Block Jacobi ILU($k$) and Parallel ILU($k$) methods.) Due to this extensibility, and also because Euclid was developed independently of the hypre project, the methods by which one passes runtime parameters to Euclid preconditioners differ in some respects from the hypre norm. While users can directly set options within their code, options can also be passed to Euclid preconditioners via command line switches and/or small text-based configuration files. The latter strategies have the advantage that users will not need to alter their codes as Euclid’s capabilities are extended.

The following fragment illustrates the minimum coding required to invoke Euclid preconditioning within hypre application contexts. The next subsection provides examples of the various ways in which Euclid’s options can be set. The final subsection lists the options, and provides guidance as to the settings that (in our experience) will likely prove effective for minimizing execution time.

```c
#include "HYPRE_parcsr_ls.h"

HYPRE_Solver eu;
HYPRE_Solver pcg_solver;
HYPRE_ParVector b, x;
HYPRE_ParCSRMatrix A;

// Instantiate the preconditioner.
HYPRE_EuclidCreate(comm, &eu);

// Optionally use the following three calls to set runtime options.
// 1. pass options from command line or string array.
HYPRE_EuclidSetParams(eu, argc, argv);

// 2. pass individual options from within your code.
HYPRE_EuclidSetParam(eu, "-level", "3");

// 3. pass options from a configuration file.
HYPRE_EuclidSetParamsFromFile(eu, "filename");

// Set Euclid as the preconditioning method for some
// other solver, using the function calls HYPRE_EuclidSetup
// and HYPRE_EuclidSolve. We assume that the pcg_solver
// has been properly initialized.
HYPRE_PCSetPrecond(pcg_solver,
                  (HYPRE_PtrToSolverFcn) HYPRE_EuclidSolve,
                  (HYPRE_PtrToSolverFcn) HYPRE_EuclidSetup,
```
eu);

// Solve the system by calling the Setup and Solve methods for,
// in this case, the HYPRE PCG solver. We assume that A, b, and x
// have been properly initialized.
HYPRE_PCGSetup(pcg_solver, (HYPRE_Matrix)A, (HYPRE_Vector)b, (HYPRE_Vector)x);
HYPRE_PCGSolve(pcg_solver, (HYPRE_Matrix)parcsr_A, (HYPRE_Vector)b, (HYPRE_Vector)x);

// Destroy the Euclid preconditioning object.
HYPRE_EuclidDestroy(eu);

7.5.2 Setting options: examples

For expositional purposes, assume you wish to set the ILU(k) factorization level to the value k = 3. There are several methods of accomplishing this. Internal to Euclid, options are stored in a simple database that contains (name, value) pairs. Various of Euclid’s internal (private) functions query this database to determine, at runtime, what action the user has requested. If you enter the option “-eu_stats 1”, a report will be printed when Euclid’s destructor is called; this report lists (among other statistics) the options that were in effect during the factorization phase.

Method 1. By default, Euclid always looks for a file titled “database” in the working directory. If it finds such a file, it opens it and attempts to parse it as a configuration file. Configuration files should be formatted as follows.

> cat database
# this is an optional comment
- level 3

Any line in a configuration file that contains a “#” character in the first column is ignored. All other lines should begin with an option name, followed by one or more blanks, followed by the option value. Note that option names always begin with a “-” character. If you include an option name that is not recognized by Euclid, no harm should ensue.

Method 2. To pass options on the command line, call

HYPRE_EuclidSetParams(HYPRE_Solver solver, int argc, char *argv[]);

where argc and argv carry the usual connotation: main(int argc, char *argv[]). If your hypre application is called phoo, you can then pass options on the command line per the following example.

mpirun -np 2 phoo -level 3

Since Euclid looks for the “database” file when HYPRE_EuclidCreate is called, and parses the command line when HYPRE_EuclidSetParams is called, option values passed on the command line
will override any similar settings that may be contained in the "database" file. Also, if same option
name appears more than once on the command line, the final appearance determines the setting.

Some options, such as "-bj" (see next subsection) are boolean. Euclid always treats these
options as the value "1" (true) or "0" (false). When passing boolean options from the command
line the value may be committed, in which case it assumed to be "1." Note, however, that when
boolean options are contained in a configuration file, either the "1" or "0" must stated explicitly.

**Method 3.** Individual options can be hardcoded via calls such as the following.

```c
HYPRE_EuclidSetParams(solver, "-level", "3");
```

**Method 4.** There are two ways in which you can read in options from a file whose name is other
than "database." First, you can call HYPRE_EuclidSetParamsFromFile to specify a configuration
filename. Second, if you have passed the command line arguments as described above in Method
2, you can then specify the configuration filename on the command line using the `-db_filename`
filename option, e.g.,

```bash
mpirun -np 2 phoo -db_filename ./myConfigFile
```

### 7.5.3 Options summary

- **level** *(int)* Factorization level for ILU(k). Default: 1. Guidance: for 2D convection-diffusion and
  similar problems, fastest solution time is typically obtained with levels 4 through 8. For 3D
  problems fastest solution time is typically obtained with level 1.

- **-bj** Use Block Jacobi ILU preconditioning instead of PILU. Default: 0 (false). Guidance: if sub-
  domains contain relatively few nodes (less than 1,000), or the problem is not well partitioned,
  Block Jacobi ILU may give faster solution time than PILU.

- **-eu_stats** When Euclid’s destructor is called a summary of runtime settings and timing information
  is printed to stdout. Default: 0 (false). The timing marks in the report are the maximum
  over all processors in the MPI communicator.

- **-eu_mem** When Euclid’s destructor is called a summary of Euclid’s memory usage is printed to std-
  out. Default: 0 (false). The statistics are for the processor whose rank in MPI_COMM_WORLD
  is 0.

- **-printTestData** This option is used in our autotest procedures, and should not normally be
  invoked by users.

The following options are partially implemented, but not yet fully functional (i.e, don’t use
them until further notice).

- **-sparseA** *(float)* Drop-tolerance for ILU(k) factorization. Default: 0 (no dropping). Entries are
  treated as zero if their absolute value is less than (sparseA * max), where “max” is the largest
  absolute value of any entry in the row. Guidance: try this in conjunction with -rowScale.
CAUTION: If the coefficient matrix \( A \) is symmetric, this setting is likely to cause the filled matrix, \( F = L + U - I \), to be unsymmetric. This setting has no effect when ILUT factorization is selected.

**-rowScale** Scale values prior to factorization such that the largest value in any row is +1 or -1. Default: 0 (false). CAUTION: If the coefficient matrix \( A \) is symmetric, this setting is likely to cause the filled matrix, \( F = L + U - I \), to be unsymmetric. Guidance: if the matrix is poorly scaled, turning on row scaling may help convergence.

**-ilut** (float) Use ILUT factorization instead of the default, ILU(\( k \)). Here, (float) is the drop tolerance, which is relative to the largest absolute value of any entry in the row being factored. CAUTION: If the coefficient matrix \( A \) is symmetric, this setting is likely to cause the filled matrix, \( F = L + U - I \), to be unsymmetric.

**-maxNzPerRow** (int) This sets the maximum number of nonzeros that is permitted in any row of \( F \), in addition to the number that would result from an ILU(\( k \)) factorization. A negative value indicates infinity (no limit). This setting is effective for both ILU(\( k \)) and ILUT factorization methods. Default: infinity, for ILU(\( k \)); 5, for ILUT.

### 7.6 PILUT: Parallel Incomplete Factorization

PILUT is a parallel preconditioner based on Saad’s dual-threshold incomplete factorization algorithm. The original version of PILUT was done by Karypis and Kumar [9] in terms of the Cray SHMEM library. The code was subsequently modified by the hypre team: SHMEM was replaced by MPI; some algorithmic changes were made; and it was software engineered to be interoperable with several matrix implementations, including hypre’s ParCSR format, PETSc’s matrices, and ISIS++ RowMatrix. The algorithm produces an approximate factorization \( LU \), with the preconditioner \( M \) defined by \( M = LU \).

**Note:** PILUT produces a nonsymmetric preconditioner even when the original matrix is symmetric. Thus, it is generally inappropriate for preconditioning symmetric methods such as Conjugate Gradient.

**Parameters:**

- **SetMaxNonzerosPerRow**( int LFIL ) ; (Default: 20) Set the maximum number of nonzeros to be retained in each row of \( L \) and \( U \). This parameter can be used to control the amount of memory that \( L \) and \( U \) occupy. Generally, the larger the value of LFIL, the longer it takes to calculate the preconditioner and to apply the preconditioner and the larger the storage requirements, but this trades off versus a higher quality preconditioner that reduces the number of iterations.

- **SetDropTolerance**( double tol ) ; (Default: 0.0001) Set the tolerance (relative to the 2-norm of the row) below which entries in \( L \) and \( U \) are automatically dropped. PILUT first drops entries based on the drop tolerance, and then retains the largest LFIL elements in each
row that remain. Smaller values of \texttt{tol} lead to more accurate preconditioners, but can also lead to increases in the time to calculate the preconditioner.
Chapter 8

Additional Information

8.1 Building the Library

Usually, hpre can be built by simply typing configure followed by make in the top-level source directory.

8.1.1 Library configuration

To automatically generate machine specific makefiles, type configure in the top level directory. The configure script is a portable script generated by GNU Autoconf. It runs a series of tests to determine characteristics of the machine on which it is running, and it uses the results of these tests to produce the machine specific makefiles, called ‘Makefile’, from template files called ‘Makefile.in’ in each directory. Once the makefiles are produced you can run make as you would with any other makefile.

The configure script primarily does the following things:

- selects a compiler
- provides either optimization or debugging options for the compiler
- finds the headers and libraries for MPI

The configure script makes these decisions based on a hierarchical check. First, it attempts to identify the machine on which it is running as a specific supported machine. Next it will try to identify the architecture as a supported architecture. If both of these fail, generic default decisions are made by the script. However, the script does have some command-line options that can give you control over the choices it will make. You can type configure --help to see the list of all of the command-line options to configure. This is the best resource for information on configure options. Below is some additional helpful information. Be aware that not all command line options have been tested on all machines and architectures, even supported machines and architectures.

--with- options Each --with- option that is listed in configure --help also was a --without- option (usually the default, but not always). Additionally, all --with- options have a
--with-option=pathname. This is not a supported feature for all --with- options however and may have no effect on configuration.

Compilers If you want to choose a compiler then it is recommended that you choose all (C, C++, Fortran) compilers.

Compiler Flags To choose optimization or debug, use --enable-opt (default) or --enable-debug. For other compiler flags use the --with-CFLAGS option.

BLAS By default, configure attempts to find the system's native optimized BLAS library. The path for this library must be in the user's PATH. To specify another library's name, use --with-Blas=pathname or --with-Blas=link list. To configure and compile without BLAS use the --without-Blas option.

Configure automatically generates a file HYPRE_config.h that includes all the header files found to be necessary by configure. This file may be used to see how a compiled version of the library was configured and may also be included by the user in his/her own code.

8.1.2 Linking to the Library

A program linking with hypre must be compiled with -I$HYPRE_DIR/include and linked with -L$HYPRE_DIR/lib -lhypre library name... -lhypre library name..., where $HYPRE_DIR is the directory where hypre is installed. Additionally, any other libraries to which hypre is linked must also be linked to by the users application. For example, the BLAS library or PETSc library are often (but not always) linked in by hypre and would also need to be linked in by the users application.

It may be useful to reference the Makefile in the test subdirectory. This makefile is designed to build test applications that link with and call hypre. All include and linking flags that are used by hypre and needed by these test applications get exported to this file by the configure script.

8.2 Calling from Fortran

Although hypre is written in C, a Fortran interface is provided. The Fortran interface is very similar to the C interface, and can be determined from the C interface by a few simple conversion rules. These conversion rules are described below.

Let us start out with a simple example. Consider the following hypre prototype:

```c
int HYPRE_IJMatrixSetValues(HYPRE_IJMatrix matrix,
    int nrows, int *ncols,
    const int *rows, const int *cols,
    const double *values);
```

The corresponding Fortran code for calling this routine is as follows:

```fortran
integer*8 matrix,
integer nrows, ncols(MAX_NCOLS)
```
8.3 Bug Reporting

HYPRE has an automated bug reporting mechanism in place that may be used as a resource for submitting bugs, desired features, and documentation problems, as well as querying the status of previous reports. Access http://www-casc.llnl.gov/bugs for full bug tracking details or to submit or query a bug report. When using the CASC bug reporting site for the first time, click on “Open a new Bugzilla account” under the “User login account management” heading.
